#### Abstract

In contrast to stable phosphorus oxides such as $\mathrm{P}_{4} \mathrm{O}_{6}$ and $\mathrm{P}_{4} \mathrm{O}_{10}$ that possess iconic adamantanelike cage structures, highly reactive phosphorus oxides such as $\mathrm{PO}, \mathrm{PO}_{2}$, and $\mathrm{P}_{2} \mathrm{O}_{x}(x=1-5)$ only have been studied in the gas phase or by matrix isolation techniques. Elusive diphosphorus tetroxide, the long sought phosphorus analogue of $\mathrm{N}_{2} \mathrm{O}_{4}$, is particularly noteworthy. Computations predict that the oxo-bridged $\mathrm{O}_{2} \mathrm{POPO}$ form of $\mathrm{P}_{2} \mathrm{O}_{4}$ is energetically more favored than the $\mathrm{P}-\mathrm{P}$ bonded $\mathrm{O}_{2} \mathrm{P}-$ $\mathrm{PO}_{2}$ isomer. Herein, we report the experimental realization of diphosphorus tetroxide-in its energetically disfavored $\mathrm{O}_{2} \mathrm{P}-\mathrm{PO}_{2}$ form-via carbene-stabilization. The synthesis of the title compound involves the splitting of molecular oxygen by carbene-stabilized diphosphorus.

The Periodic Table suggests that elements in the same group generally exhibit similar chemical properties. Although phosphorus resides immediately beneath nitrogen on the Periodic Table, the chemical behavior of these two elements is quite different. This disparity is not only evident for the elements, but it also extends to the compounds of these first two pnictogens. ${ }^{1}$ For example, nitrogen gas $\left(\mathrm{N}_{2}\right)$ is both tremendously stable and ubiquitous (making up nearly $80 \%$ of the earth's atmosphere). In contrast, diphosphorus ( $\mathrm{P}_{2}$ ) is transient and generally only observed at high temperatures. ${ }^{1}$ Furthermore, nitrogen readily forms a series of isolable oxides, (such as $\mathrm{NO}, \mathrm{NO}_{2}, \mathrm{~N}_{2} \mathrm{O}_{x}(x=1,3,4,5)$ ) that have had a profound impact on both our environment and various aspects of the human experience. ${ }^{2}$ The stable oxides of phosphorus, such as $\mathrm{P}_{4} \mathrm{O}_{6}$ and $\mathrm{P}_{4} \mathrm{O}_{10}$, contain iconic adamantane-like cores. ${ }^{1}$ However, the phosphorus congeners of those isolable nitrogen oxides [i.e., $\mathrm{PO}, \mathrm{PO}_{2}, \mathrm{P}_{2} \mathrm{O}_{x}(x=1,3,4,5)$ ] are highly reactive and typically only studied in the gas phase or in matrix isolation experiments at cryogenic temperatures. ${ }^{3}$ Consequently, synthetic applications of these reactive phosphorus oxides are severely limited.

The first transition metal compounds containing phosphorus monoxide ( PO ) and diphosphorus monoxide ( $\mathrm{P}_{2} \mathrm{O}$ ) were reported more than two decades ago. ${ }^{4,5}$ However, alternative synthetic strategies are imperative to develop the largely unexplored chemistry of these extremely reactive phosphorus oxides. In this regard, diphosphorus tetroxide, $\mathrm{P}_{2} \mathrm{O}_{4}$, is particularly intriguing. Computations suggest that $\mathrm{P}_{2} \mathrm{O}_{4}$ energetically favors an oxo-bridged, nonplanar $\mathrm{O}_{2} \mathrm{POPO}$
structure (with $C_{s}$ symmetry), rather than its $\mathrm{O}_{2} \mathrm{P}-\mathrm{PO}_{2}$ isomer. ${ }^{6,7}$ In contrast, dinitrogen tetroxide $\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)$ exists as a weakly $\mathrm{N}-\mathrm{N}$-bonded $\mathrm{O}_{2} \mathrm{~N}-\mathrm{NO}_{2}$ dimer. ${ }^{1}$ Whether $\mathrm{P}_{2} \mathrm{O}_{4}$ can be stabilized as an analogue of $\mathrm{N}_{2} \mathrm{O}_{4}$ (in the $\mathrm{O}_{2} \mathrm{P}-\mathrm{PO}_{2}$ form) clearly represents a fascinating synthetic challenge. Carbenestabilization has recently emerged as a remarkably effective synthetic strategy in the isolation of highly reactive, lowoxidation state, main group molecules. ${ }^{8-13}$ This laboratory previously reported the synthesis of carbene-stabilized diphosphorus, $\mathrm{L}: \mathrm{P}-\mathrm{P}: \mathrm{L},(\mathrm{L}:=\mathrm{N}$-heterocyclic carbene; : $\mathrm{C}\{\mathrm{N}-$ $\left.\left.\left(2,6-\mathrm{Pr}_{2}{ }_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right) \mathrm{CH}\right\}_{2}\right)(2)^{14}$ by potassium graphite reduction of $\mathrm{L}: \mathrm{PCl}_{3}(1) .{ }^{15}$ Herein, we report the synthesis, ${ }^{16}$ molecular structure, ${ }^{16}$ and computational analysis ${ }^{17}$ of carbene-stabilized diphosphorus tetroxide $\mathrm{L}:(\mathrm{O})_{2} \mathrm{P}-\mathrm{P}(\mathrm{O})_{2}: \mathrm{L}$ (3), which is obtained via the splitting of molecular oxygen by compound 2. Phosphorus oxides are well documented as Lewis bases bonding to transition metals ${ }^{18,19}$ or main group elements. ${ }^{20,21}$ Notably, compound 3 represents the first example of a phosphorus oxide exhibiting Lewis acidic behavior.

Transition metal complexes have long dominated the chemistry of dioxygen binding and activation due to their critical role in oxygenation in various biological systems. ${ }^{22}$ However, electron-rich main group species may also activate triplet $\mathrm{O}_{2}$ molecules. For instance, autoxidation mechanisms have been proposed in the transformation of phosphanylidenephosphoranes ( $\mathrm{RP}=\mathrm{PR}_{3}$ ) into diphosphenes. ${ }^{23}$ The synthesis of long-pursued sila-ureas, via silicon(II)-based dioxygen activation, has also been reported. ${ }^{24}$ Inspired by the classic oxidation of white phosphorus to $\mathrm{P}_{4} \mathrm{O}_{10}{ }^{1}{ }^{1}$ we allowed (redcolored) 2 to react with dioxygen in toluene [at temperatures ranging from $-6{ }^{\circ} \mathrm{C}$ to room temperature ( $25{ }^{\circ} \mathrm{C}$ )], giving compound 3 in $54 \%$ yield (Scheme 1). Although the

## Scheme 1. Synthesis of compound 3

Received: November 15, 2013
Published: December 3, 2013
mechanistic details in the formation of 3 are unclear, the splitting of triplet $\mathrm{O}_{2}$ by the singlet $\mathrm{P}_{2}$ core in 2 may involve a single-electron transfer mechanism. ${ }^{22}$ Indeed, single-electron oxidation has been reported for carbene-stabilized $\mathrm{P}_{2}$ molecules (including 2). ${ }^{25}$

Colorless X-ray quality crystals of 3 were obtained by recrystallization in toluene (under an oxygen- and water-free argon atmosphere). However, crystals of $3 \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ were obtained when the recrystallization proceeded in air. While $\mathrm{N}_{2} \mathrm{O}_{4}$ exists in an equilibrium mixture of $\mathrm{NO}_{2}$ at $25{ }^{\circ} \mathrm{C}$ (dissociation energy of $\mathrm{N}_{2} \mathrm{O}_{4}: 14 \mathrm{kcal} / \mathrm{mol}$ ), ${ }^{1}$ compound 3 is sufficiently stable such that dissociation to $\mathrm{L}: \mathrm{PO}_{2}$ was not observed (dissociation energy of 3: $49 \mathrm{kcal} / \mathrm{mol}$ ). ${ }^{17}$ It is noteworthy that the synthesis of 3 is extremely moisture- and temperature-sensitive. Improving the anhydrous nature of $\mathrm{O}_{2}$ and conducting the preparation at low temperature effectively increases the yield of 3 .

Compound 3 was characterized by elemental analysis, infrared spectroscopy, ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}$ NMR, and single-crystal X-ray diffraction. ${ }^{16}$ The imidazole ${ }^{1} \mathrm{H}$ NMR resonance of 3 shifts to 6.25 ppm from 5.98 ppm for $2 .{ }^{14}$ Meanwhile, the ${ }^{1} \mathrm{H}$ coupled ${ }^{31} \mathrm{P}$ NMR singlet resonance of 3 dramatically shifts downfield to 5.8 ppm from -52.4 ppm for $2,{ }^{14}$ which is due to the electronegative oxygen atoms in 3 attracting the electron density away from the central phosphorus atoms. The infrared (IR) spectrum of 3 exhibits two characteristic $\mathrm{PO}_{2}$ stretching frequencies at $1279 \mathrm{~cm}^{-1}$ (antisymmetric mode) and 1061 $\mathrm{cm}^{-1}$ (symmetric mode), which compare well to the computed frequencies ( $1290 \mathrm{~cm}^{-1}$ and $1061 \mathrm{~cm}^{-1}$ ) of $\mathrm{PO}_{2}$ in $3\left(C_{i}\right.$ symmetry), respectively. ${ }^{17}$ Notably, due to the intermolecular hydrogen bonds involving the lattice water and the oxygen atoms of the $\mathrm{O}_{2} \mathrm{P}-\mathrm{PO}_{2}$ core (Figure S 1 , Supporting Information [SI]), the stretching frequencies of $\mathrm{PO}_{2}$ for 3 . $\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ are red-shifted to $1269 \mathrm{~cm}^{-1}$ (antisymmetric mode) and $1057 \mathrm{~cm}^{-1}$ (symmetric mode).

The crystal structure of 3 reveals that this compound possesses $C_{i}$ symmetry and contains an unprecedented $\mathrm{O}_{2} \mathrm{P}-$ $\mathrm{PO}_{2}$ core that adopts a trans-bent geometry due to the coordination of two bulky carbene ligands (Figure 1). It is instructive to delineate the structural effects of capping the diphosphorus core in 2 with four oxygen atoms. Each phosphorus atom in 3 , in the formal oxidation state of +4 , is four-coordinate and resides in a distorted tetrahedral geometry, whereas each phosphorus atom in 2 , in the formal oxidation state of zero, is two-coordinate and adopts a bent geometry. The $C(1)-P(1)-P(1 A)-C(1 A)$ torsion angles in both 2 and 3 are $180^{\circ} .{ }^{14}$ The $\mathrm{C}(1)-\mathrm{P}(1)-\mathrm{P}(1 \mathrm{~A})$ bond angle $\left[102.08(11)^{\circ}\right]$ in 3 is only marginally less than that $\left[103.19(6)^{\circ}\right]$ in 2 . The $P-$ $P$ bond of 3 [ $2.310(2) \AA]$ is about $0.1 \AA$ longer than that in 2 [2.2052(10) $\AA$ ] which, however, is almost the same as that [2.3103(7) $\AA$ ] in a "Jack-in-the-Box" diphosphine. ${ }^{26}$ The P-C bond distance $[1.895(3) \AA]$ in 3 , corresponding to the typical $\mathrm{P}-\mathrm{C}$ single bond distance [i.e., the $1.871(11) \AA \mathrm{P}-\mathrm{C}$ bond distance in 1], ${ }^{15}$ is about $0.13 \AA$ longer than that [1.7504(17) $\AA]$ in $2,{ }^{14}$ which may be attributed to the lack of P-to-C $\mathrm{C}_{\mathrm{NHC}} \mathrm{p} \pi$ back-donation in 3. The $\mathrm{P}-\mathrm{O}$ bond distances [1.466(3) and $1.470(3) \AA$ in 3 are comparable to the computed $\mathrm{P}-\mathrm{O}$ bond distance $(1.437 \AA)$ in $\mathrm{O}_{2} \mathrm{P}-\mathrm{PO}_{2}$ with $D_{2 d}$ symmetry, ${ }^{6}$ the experimental $\mathrm{P}-\mathrm{O}$ bond distances in $\mathrm{L}^{\prime}: \mathrm{P}(\mathrm{O})_{2} \mathrm{Cl}[1.452(2) \AA$, $\left.\mathrm{L}^{\prime}:=: \mathrm{C}\{(i-\operatorname{Pr}) \mathrm{NC}(\mathrm{Me})\}_{2}, 4\right],{ }^{27}$ and in phosphine oxides (i.e., $1.48 \AA$ for $\left.\mathrm{Ph}_{3} \mathrm{PO}\right) .^{28}$ In contrast, it is obviously shorter than the $\mathrm{P}-\mathrm{OH}$ bond distance $\left[1.5750(15) \AA\right.$ ] in $\mathrm{L}^{\prime}: \mathrm{P}(\mathrm{O})_{2} \mathrm{OH}^{29}$ and the sum of phosphorus and oxygen covalent radii (1.73

Figure 1. Molecular structure of $\mathrm{L}:(\mathrm{O})_{2} \mathrm{P}-\mathrm{P}(\mathrm{O})_{2}: \mathrm{L}(\mathrm{L}:=: \mathrm{C}\{\mathrm{N}(2,6-$ $\left.\left.\operatorname{Pr}_{2}^{i} \mathrm{C}_{6} \mathrm{H}_{3}\right) \mathrm{CH}\right\}_{2}$ ) (3) (thermal ellipsoids represent $30 \%$ probability; hydrogen atoms omitted for clarity). Selected bond distances $(\AA)$ and angles (deg). For 3, $\mathrm{P}(1)-\mathrm{P}(1 \mathrm{~A}) 2.310(2), \mathrm{P}(1)-\mathrm{C}(1) 1.895(3)$, $\mathrm{P}(1)-\mathrm{O}(1) \quad 1.466(3), \mathrm{P}(1)-\mathrm{O}(2) \quad 1.470(3), \mathrm{C}(1)-\mathrm{P}(1)-\mathrm{P}(1 \mathrm{~A})$ $102.08(11), \quad \mathrm{O}(1)-\mathrm{P}(1)-\mathrm{P}(1 \mathrm{~A}) \quad 107.68(15), \quad \mathrm{O}(2)-\mathrm{P}(1)-\mathrm{P}(1 \mathrm{~A})$ 109.57(14), $\mathrm{O}(1)-\mathrm{P}(1)-\mathrm{O}(2) \quad 125.39(19), \mathrm{O}(1)-\mathrm{P}(1)-\mathrm{C}(1)$ 103.28(14), $\mathrm{O}(2)-\mathrm{P}(1)-\mathrm{C}(1)$ 106.27(15). For $3 \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}, \mathrm{P}(1)-$ $\mathrm{P}(1 \mathrm{~A}) 2.2132(13), \mathrm{P}(1)-\mathrm{C}(1) 1.876(2), \mathrm{P}(1)-\mathrm{O}(1) 1.458(2)$, $\mathrm{P}(1)-\mathrm{O}(2) 1.467(2), \mathrm{C}(1)-\mathrm{P}(1)-\mathrm{P}(1 \mathrm{~A}) 102.51(8), \mathrm{O}(1)-\mathrm{P}(1)-$ $\mathrm{P}(1 \mathrm{~A}) \quad 109.42(11), \mathrm{O}(2)-\mathrm{P}(1)-\mathrm{P}(1 \mathrm{~A}) \quad 109.55(11), \mathrm{O}(1)-\mathrm{P}(1)-$ $\mathrm{O}(2) 122.12(16), \mathrm{O}(1)-\mathrm{P}(1)-\mathrm{C}(1) 105.65(11), \mathrm{O}(2)-\mathrm{P}(1)-\mathrm{C}(1)$ 105.68(11).
$\AA$ ), ${ }^{30}$ suggesting the multiple-bond character of the phospho-rus-oxygen bonds in 3 . The $\mathrm{O}-\mathrm{P}-\mathrm{O}$ bond angle $\left[125.39(19)^{\circ}\right]$ in 3 compares well to that $\left[124.16(15)^{\circ}\right]$ in $4 .{ }^{27}$

In the crystal of $3 \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}{ }^{16}$ molecule 3 (also with $C_{i}$ symmetry) exhibits somewhat different structural parameters (Figure 1, caption). This may be due to the packing effects and the hydrogen bonding interactions between lattice water molecules and 3 (Figure S1 in SI). Notably, the P-P bond [2.2132(13) $\AA$ ] for $3 \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ is about $0.1 \AA$ shorter than that $[2.310(2) \AA]$ of the nonsolvated 3 , which indicates the flexibility of the $\mathrm{P}-\mathrm{P}$ bond of compound 3 . The $\mathrm{P}-\mathrm{O}$ bond distances $[1.458(2)$ and $1.467(2) \AA]$ in $3 \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$, however, are only little bit shorter than those in the nonsolvated 3 [1.466(3) and $1.470(3) \AA]$. As shown in the space-filling model of 3 . $\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ (Figure S1 in SI), the steric bulk of the carbene ligands can effectively shield the $\mathrm{P}_{2} \mathrm{O}_{4}$ core and only allow two lattice water molecules to achieve hydrogen bonds with two of the four oxygen atoms of 3 .

The nature of 3 was further probed by density functional theory (DFT) computations at the B3LYP/DZP level. ${ }^{17}$ The optimized 3 in $C_{i}$ symmetry (Figure S3 in SI) corresponds to a rotational transition state, which is only $2.9 \mathrm{kcal} / \mathrm{mol}$ higher in energy than the $C_{1}$ minimum (Figure S2 in SI) of 3 . The packing effects may play a contributing role in the $C_{i}$ conformation experimentally observed in the solid state of 3 . The computed structural parameters (i.e., $d_{\mathrm{P}-\mathrm{P}}=2.231 \AA, d_{\mathrm{P}-\mathrm{O}}$ $=1.501 \AA \AA, d_{\mathrm{P}-\mathrm{C}}=1.928 \AA, \mathrm{O}-\mathrm{P}-\mathrm{O}$ bond angle $\left.=123.56^{\circ}\right)$ of 3 ( $C_{i}$ symmetry) are comparable to the experimental results for both 3 and $3 \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}{ }^{16^{6}}$

The localized molecular orbitals (LMOs) of the simplified model 3-H [L: $=: \mathrm{C}(\mathrm{NHCH})_{2}$; optimized in $\mathrm{C}_{i}$ symmetry, Figure S4 in SI] are shown in Figure 2. Natural bond orbital (NBO) analysis shows that one lone pair orbital of oxygen has mainly $s$-character ( $65.4 \%$, av.), while another two lone pair orbitals of oxygen are essentially pure $p$-character ( $99.6 \%$, av), which are somewhat distorted toward phosphorus. The central

Figure 2. Localized molecular orbitals (LMOs) of 3-H with $C_{i}$ symmetry. (a) $\mathrm{P}-\mathrm{P} \sigma$-bonding orbital; (b) $\mathrm{P}-\mathrm{C} \sigma$-bonding orbital; (c) $\mathrm{P}-\mathrm{O} \sigma$-bonding orbital; (d, e, f) lone pair orbitals of O .
$\mathrm{P}-\mathrm{P}$ bond in 3-H has mainly $p$-character ( $22 \% s, 76 \% p, 2 \% d$ ). The Wiberg bond indices (WBIs) ( $\mathrm{P}-\mathrm{P}, 0.673$; $\mathrm{P}-\mathrm{C}, 0.678$ ) of 3-H are lower than those ( $\mathrm{P}-\mathrm{P}, 1.004 ; \mathrm{P}-\mathrm{C}, 1.397$ ) for 2 , indicating relatively weak $\mathrm{P}-\mathrm{P}$ and $\mathrm{P}-\mathrm{C}$ bonds in $3-\mathrm{H}$. The $\mathrm{P}-$ $\mathrm{O} \sigma$-bond polarization is $75 \%$ toward oxygen and $25 \%$ toward phosphorus. The WBI values of the $\mathrm{P}-\mathrm{O}$ bonds $(1.14, \mathrm{av})$ in 3$\mathbf{H}$ suggest modest multiple bond character of the $\mathrm{P}-\mathrm{O}$ bonds. For the $\mathrm{PO}_{2}$ unit in $3-\mathrm{H}$ phosphorus bears +1.8 positive charge, while each oxygen bears -1.1 negative charge. When considering the experimental data and theoretical analysis, two extreme resonance forms ( $3 \mathbf{A}$ and $\mathbf{3 B}$ ) may be proposed for 3 (Scheme 2, $\mathrm{R}=2,6-\operatorname{Pr}_{2}^{i} \mathrm{C}_{6} \mathrm{H}_{3}$ ).

Scheme 2. Two Contributing Canonical Resonance Structures of 3

The synthesis of 3 through splitting molecular oxygen by carbene-stabilized $P_{2}$ suggests a new strategy to probe the exciting chemistry of highly reactive phosphorus oxides.
